Class 6: R functions

Edwin Ruiz (PID: A17136339)

Functions are how we get work done in R. We call functions to do everything from reading data to doing analysis and outputting plots and results.

All functions in R have at least 3 things:

- a **name** (we pick this)
- input **arguments** (there can only be one or loads again we get the call on this)
- the **body** (where the work gets done, this code between the curly brackets)

A first silly function

Let's write a function to add some numbers. We can call it add()

```
x <- 10
y <- 10
x + y

[1] 20

add <- function(x) {
   y <- 10
   x + y
}</pre>
```

Can I just use my new function?

```
add(1)
```

[1] 11

Let's make it a bit more flexible

```
add <- function(x, y=1) {
    x + y
}
add(10,10)

[1] 20
add(10)

[1] 11
add(10, 100)</pre>
```

2nd Example grade() function

Write a function to grade student work

We will start with a simple version of the problem and the following example student vectors:

```
# Example input vectors to start with
student1 <- c(100, 100, 100, 100, 100, 100, 90)
student2 <- c(100, NA, 90, 90, 90, 90, 97, 80)
student3 <- c(90, NA, NA, NA, NA, NA, NA, NA)

Start with student1
mean(student1)

[1] 98.75

mean(student2, na.rm = TRUE)</pre>
```

```
mean(student3, na.rm = TRUE)
[1] 90
Okay lets try to work with student1 and drop the lowest score
  student1
[1] 100 100 100 100 100 100 100 90
Google told us about min() and max()
  min (student1)
[1] 90
  which.min(student1)
[1] 8
  student1[8]
[1] 90
  student1[ which.min(student1) ]
[1] 90
  student1[-8]
[1] 100 100 100 100 100 100 100
  mean(student1[-8])
[1] 100
```

Our first working snippet that drops the lowest score and calculates the mean

```
mean(student1[ -which.min(student1)])
```

[1] 100

```
x <- student2
mean(x[ -which.min(x)], na.rm=T)</pre>
```

[1] 92.83333

Our approach to the NA problem (missing homeworks): We can replace all NA values with zeros

1st task is find the NA values (i.e where are they in the vector)

```
x
[1] 100 NA 90 90 90 90 97 80
```

is.na(x)

[1] FALSE TRUE FALSE FALSE FALSE FALSE FALSE

I have found the NA (TRUE) values from is.na() now I want to equal them into a zero (mask/overwrite them)

```
y <- 1:5
y
```

[1] 1 2 3 4 5

```
y [y>3] <- 0
y
```

[1] 1 2 3 0 0

I want to combine the is.na(x) with making these elements equal to zero. And then this "masked" (vector of student scores with NA values as zero) and drop the lowest and get the mean.

```
x <- student2
x[is.na(x)] <- 0
mean(x[-which.min(x)])

[1] 91

x <- student3
x[is.na(x)] <- 0
mean(x[-which.min(x)])

[1] 12.85714

x <- student1
x[is.na(x)] <- 0
mean(x[-which.min(x)])

[1] 100

Now I can turn this snippet into my first function.

grade <- function(x) {</pre>
```

```
grade <- function(x){
    # Make NA (missing work) equal to zero
    x[is.na(x)] <- 0
    # Drop lowest score and get mean
    mean(x[-which.min(x)])</pre>
```

grade(student3)

[1] 12.85714

}

Q1. Write a function grade() to determine an overall grade from a vector of student homework assignment scores dropping the lowest single score. If a student misses a homework (i.e. has an NA value) this can be used as a score to be potentially dropped. Your final function should be adquately explained with code comments and be able to work on an example class gradebook such as this one in CSV format: "https://tinyurl.com/gradeinput".

```
url <- "https://tinyurl.com/gradeinput"
gradebook <- read.csv(url, row.names = 1)
head(gradebook)</pre>
```

```
hw1 hw2 hw3 hw4 hw5
student-1 100
                73 100
                         88
                             79
student-2
            85
                64
                         89
                             78
                    78
student-3
            83
                69
                    77 100
                             77
student-4
            88
                NA
                    73 100
                             76
            88 100
student-5
                    75
                         86
                             79
student-6
            89
                78 100
                         89
                             77
```

The apply() function in R is super useful but can be a little confusing to begin with. Lets have a look at how it works.

```
ans <- apply(gradebook, 1, grade)
ans</pre>
```

```
student-1
            student-2
                        student-3
                                   student-4
                                               student-5
                                                           student-6
                                                                      student-7
     91.75
                82.50
                            84.25
                                        84.25
                                                   88.25
                                                                           94.00
                                                               89.00
 student-8
            student-9 student-10 student-11 student-12 student-13 student-14
     93.75
                87.75
                            79.00
                                        86.00
                                                   91.75
                                                               92.25
                                                                           87.75
student-15 student-16 student-17 student-18 student-19 student-20
                89.50
     78.75
                            88.00
                                        94.50
                                                   82.75
                                                               82.75
```

Q2. Using your grade() function and the supplied gradebook, Who is the top scoring student overall in the gradebook?

```
which.max(ans)
student-18
18
max(ans)
```

[1] 94.5

Q3. From your analysis of the gradebook, which homework was toughest on students (i.e. obtained the lowest scores overall?

```
apply(gradebook, 2, mean, na.rm=TRUE)
                                            hw5
     hw1
               hw2
                        hw3
                                  hw4
89.00000 80.88889 80.80000 89.63158 83.42105
  HW <- apply(gradebook, 2, mean, na.rm=TRUE)</pre>
  which.min(HW)
hw3
  3
     Q4. Optional Extension: From your analysis of the gradebook, which homework
     was most predictive of overall score (i.e. highest correlation with average grade
     score)?
  #ans
  cor(gradebook$hw1, ans)
[1] 0.4250204
  cor(gradebook$hw5, ans)
[1] NA
  gradebook$hw5
 [1]
              77
                  76 79 77 100 100 77 76 100 100 80 76 NA 77 78 100 79
[20]
      76
Make all NA values into zero
  mask <- gradebook
  mask[is.na(mask)] <- 0</pre>
```

```
cor(mask$hw5, ans)
```

[1] 0.6325982

5

Now we can use <code>apply()</code> to examine the correlation of every assignment in the masked grade-book to the overall score for each student in the class

```
apply(mask, 2, cor, y=ans)

hw1  hw2  hw3  hw4  hw5
0.4250204 0.1767780 0.3042561 0.3810884 0.6325982

corr <- apply(mask, 2, cor, y=ans)

which.max(corr)</pre>
```
